Immediate vs. delayed loading in oral restauration on multiple dental implants

The tendency in dental care today is more and more toward total mouth restauration using dental implants. Surgical techniques like All-on-four or fast and fix are increasingly demanded by the patients, sometimes without even a proper clinical indication. The implants brought a significant improvement in life quality of our patients, mostly those of a certain age wearing removable prosthesis, who's condition enhanced after the placement of an overdenture on dental implants. We are presenting here a number of clinical cases with patients of a wide range of ages, from simple to complex, with follow up of several years. Rate of success is in the range mentioned in literature 93-95%, with long term survival of the implants with immediate, as well as delayed loading in the same proportion. The manner of the prosthetic fixation and the number of the implants and prosthetic loading is highly dependent of the area/country where the surgery is done, as well as the esthetic and functional demands. The 3 groups considered, dental implants in the same session with the extraction, dental implants on a healed bone crest and the implants with immediate loading are in the same range of survival rate, based on the clinical cases considered in the last 12 years.

Biography

Lorelei Nassar has 26 year experience in Dentistry, among them 20 in Oral and Maxillo Facial Surgery and Implantology. She is the Founder of 2 companies, AB Dental Romania and Clinica De Implantologie.
