Survey on public awareness regarding the magnitude of surgical dentistry

T Sai Prabhath

NTR University of Health Sciences, India

A survey about the public awareness towards the magnitude of oral and maxillofacial surgery is conducted. The sole purpose of this survey is to analyze the percentage of people who are aware about the various types of treatments and conditions related to oral health. The survey is followed by analysis and then articles written briefly about the most prevalent problems seen related to oral cavity and their reflective treatment plan. This makes it easy for the general population to have an understanding about the treatment options which in turn makes it easier for all the dentists, as this would help the patient in self-motivation, especially when it comes to the implant therapy. The prime reason being long duration of the treatment plan, other common reasons were because of the need for surgery, etc. Along with that it also helps us understand the knowledge of the general public about the treatments that a dentist can offer. As we know that most of the public are not aware of the latest advancements and procedures, from this survey we can evaluate the extent of their knowledge.
