Room temperature ionic liquids (RTILs) are salts with melting points close or below room temperature, 30°C. Most polymers in the industry have shown to display hydrophilic characteristics, which have had more scientists paying much attention for membrane electrolyte during the past few years. The first work to become published in the study for solid polymer electrolyte was carried out by Wright and co-workers [1,2] and was devoted to the ionic nature for their conducting behavior. Scientists have used ionic liquids, also known as plasticizers, as organic solvents and supporting electrolytes in many fields due to their exceptional properties like high conductivity, non-volatility, non-flammability, etc. [3-8]. Due to the significant development of plasticizers to the conductivity, thermal and electrochemical properties of polymers, the merging of plasticizers into different polymers has been reported [9-11]. In order to overcome the brittleness of polymer films, the addition of plasticizers is important to improve flow and flexibility, and to increase toughness, to impact resistance of film coating, and to prevent them from cracking during packaging and transportation [12, 13]. The compatibility and permanence is normally based on the selection of plasticizer for a specified system, the amount needed for plasticization, and the desired physical properties of the films [14].

Ionic liquids when blended with polymers show a promising class of new materials with a bright technological future. The blends are now being used in application that are enabled by their presence, as well as in application where device or process performance outweighs their higher cost.

The main driving force to explore ionic liquids is the fact that these compounds have a very low vapor pressure, so that they are candidates to replace volatile organic solvents in organic reactions, because the properties of ionic liquids (miscibility with water and other solvents, dissolving ability, polarity, viscosity, density) can be tuned by an appropriate choice of the anion and the cation. Ionic liquids are often considered as designer solvents. These ionic liquids can also be used to immobilize transition metal catalysts in the liquid phase of biphasic catalytic reactions. Other applications include their use as solvents for extraction processes and as an electrolyte for batteries, fuel cells, and dye-sensitized solar cells. Also they are neutral organic compounds. Ionic liquid are a class of liquid salt that contain anions and cations. The ionic character means that some of the properties of the ionic liquid differ significantly from that of conventional organic liquids.

Polymeric microelectronic devices such as memory devices, sensors and fuel cells, require conductive polymers in its composition. Doping polymers with iodine and arsenic to modulate the electrical conductivity have been reported in recent years. However, doping non-conductive polymers with organic plasticizer to modulate their electrical conductivity just emerged in recent years. Ayesha et al. [15], reported doping poly (vinyl alcohol) (PVA) thin films with various ratios (0-5% w/w) of 1-methyl-3-n-decyl-imidazolium bromide ionic liquid [MDIM] (+)Br(-). PVA is a hydrophilic semi-crystalline polymer produced by polymerization of vinyl acetate monomer to form poly (vinyl acetate) (PVAc), and subsequent hydrolysis of PVAc to form PVA [16]. PVA is soluble in water. When formed as thin films, the properties of PVA are extremely affected by the molecular weight and the degree of hydrolysis [17]. The AC impedance measurements were conducted for

a frequency range of 10-10<sup>6</sup> Hz as a function of temperature between 298-425 K. The results showed that the resistivity of the thin film decreases as the dopant ratio increases. The results also showed that the film relaxation time decreases as the dopant ratio increases. Increasing the film temperature was found to decrease the resistivity of the films due to the increase in charge carrier concentration. The films activation energy is adjusted by tuning the dopant concentration in the blend.

Josh et al. [18], reported the electrical properties of polymer membrane made out of blending PVA, poly (acrylamide-co-acrylic acid) (PAA) and varying ratio (0-5% w/w) of sorbitol. It was observed that as the temperature increases, the resistivity decreases in general for polymer films. In addition, increasing the doping concentration decreases the resistivity. The results showed a systematic decrease in the resistivity with the increase of doping concentration. The activation energy decreases with increasing the sorbitol concentration. The relaxation time decreases with temperature. At high frequency range, the conductivity is dominated by the ionic conduction process in the bulk of the polymer electrode [19-21].

The effect of ionic liquid on the polymer segmental and conductivity depends on the specific nature of the ionic liquid, including viscosity, dielectric constant and polymer-ionic liquid interaction.

A key application for the new classes of conductive polymers lies in the polymeric memory devices. A polymeric memory device generally consists of sandwiched conductive terminals, semiconducting material and storage element (usually nanoparticles). Haik [21] employed the conductive characteristics of polymeric blends made out of PVA, PAA and glycerol ionic liquid as semiconductors. Single wall carbon nanotubes were used as storage element. Double sweep capacitance-voltage tests were carried out to identify memory properties of the organic semiconductor devices. The 2% mixture of the ionic liquids glycerol was used. When CNT was introduced, it gave a significant window gate of  $\pm 20$  V, indicating that there is no leak in the system.

The ionic liquids as dopant to modulate conductivity in non-conductive polymers are promising and it is anticipated that new applications will emerge that takes advantages of these inexpensive conductive polymers.
